

Allylic Halogenation

2 New Ideas

\Rightarrow Radicals easily form on the carbons adjacent to a pi bond (C=C)

B) When given a choice in allylic halogenation reactions you always make the most stable alkene product

How to think about allyl radicals and allyl cations

Allylic Halogenation

Initiation

Propagation

Termination

When analyzing allylic halogenation reactions (NBS and hv)

1. Consider all possible allylic radicals that can be formed.
2. Analyze all contributing structures for all of the allylic radicals.
3. Add a Br atom at the site of the unpaired electron for all contributing structures for all of the allylic radicals.
4. From all of the possible products, the predominant product is the one THAT IS THE MOST STABLE ALKENE – the most substituted alkene – alkyl groups stabilize alkenes – *trans* over *cis*.
5. Note: It is OK if the product you choose derives from an allylic radical contributing structure that is a minor contributor. FOR THIS REACTION WE ONLY CARE ABOUT THE RELATIVE STABILITIES OF THE PRODUCT ALKENES.

Big Change — For this reaction you need to choose the most stable product, NOT worrying about the most stable contributing structure of an allylic radical intermediate. ⁹⁹⁾

Non-Markovnikov Addition of HBr to an Alkene

Initiation

Propagation

Termination

For subtle reasons (not discussed) H-Br, ROOR and heat gives very little allylic halogenation, and NBS/hv or heat gives very little alkene addition even though they both involve $[\cdot\ddot{\text{Br}}:]$ and an alkene starting material.

Making Haloalkanes

Never use
 Br_2 and $h\nu$
or heat
with an
alkene!

New Concept → Leaving Group

A group that can
make a single bond
to carbon that can
make a stable species
when it departs

1
nucleophiles/bases

Halogens

I > Br > Cl > F

← Leaving Group Ability

← Anion Stability

Not much
of a
leaving
group

1st New Mechanism

S_N2 ← Bimolecular → both the
haloalkane and
nucleophile are
involved in the
rate-determining
(slow) step of
the reaction

Substitution →

↑ Nucleophilic

The S_N2 Mechanism

Nucleophile \rightarrow must attack at the back of the C-Br bond. \Rightarrow This angle and direction of attack helps break the C-Br bond

The configuration at this carbon atom is inverted

Summary: The nucleophile attacks by making a new bond to C from the back of the C-X bond just as X leaves

Regiochemistry: **N/A**

Stereochemistry: **INVERSION** at the site of reaction

Example:
