

## Table of Nucleophiles

<b>Strong Nucleophiles</b> $\text{Br}^-$ , $\text{I}^-$ , $\text{R-S}^-$ , $\text{H-S}^-$ , $\text{N}\equiv\text{C}^-$ , $\text{N}_3^-$ $\text{R-C}\equiv\text{C}^-$ , $\text{R-O}^-$ , $\text{H-O}^-$ <b>Strong Bases</b>
<b>Medium Nucleophiles</b> $\text{R-CO}_2^-$ , $\text{R-S-H}$ , $\text{R}_2\text{S}$ , $\text{NH}_3$ , $\text{RNH}_2$ , $\text{R}_2\text{NH}$ , $\text{NR}_3$
<b>Weak Nucleophiles</b> $\text{R-CO}_2\text{H}$ , $\text{R-O-H}$ , $\text{H}_2\text{O}$ <b>Very Weak Bases</b>

### Special Case

Tert-Butoxide ( $\text{tBuO}^-$ ) is a strong base, but is not a nucleophile due to steric hindrance.

" $\text{KOtBu}$ "  
or  
" $\text{tBuO}^-$ "

## Substitution/Elimination Decision Map

Methyl Halide  $\Rightarrow$   $S_N2$

Primary Haloalkane  $\Rightarrow$   $t\text{BuOK ?}$   $\Rightarrow$  Yes  $\Rightarrow$  E2  
 No  $\Rightarrow$   $S_N2$

Secondary Haloalkane  
 or  
 Allylic/Benzylic Halides  $\Rightarrow$  Very Weak Base ?  $\Rightarrow$  Yes  $\Rightarrow$   $S_N1/E1$  \*  
 Very Strong Base ?  $\Rightarrow$  Yes  $\Rightarrow$  E2 \*\*  
 No  $\Rightarrow$   $S_N2$

Tertiary Haloalkane  $\Rightarrow$  Very Weak Base ?  $\Rightarrow$  Yes  $\Rightarrow$   $S_N1/E1$   
 No  $\Rightarrow$  E2

For  $S_N2$  Remember Chiral Center INVERSiON  
 For E2 Remember anti-periplanar and Zaitsev  
 For  $S_N1$  Remember Chiral Center Scrambling  
 For E1 Remember Zaitsev

\* Note: With Very Weak Bases,  $S_N2$  can compete here, but for the purposes of this class, assume  $S_N1 / E1$  predominate

\*\* Note: If  $t\text{BuOK}$  is the very strong base, an appreciable amount of a non-Zaitsev product can be formed because the bulky  $t\text{BuOK}$  will tend to react with the most accessible H atom.

## Substitution vs. Elimination Examples:

Methyl Haloalkanes (CH<sub>3</sub>X) → Only S<sub>N</sub>2 is possible

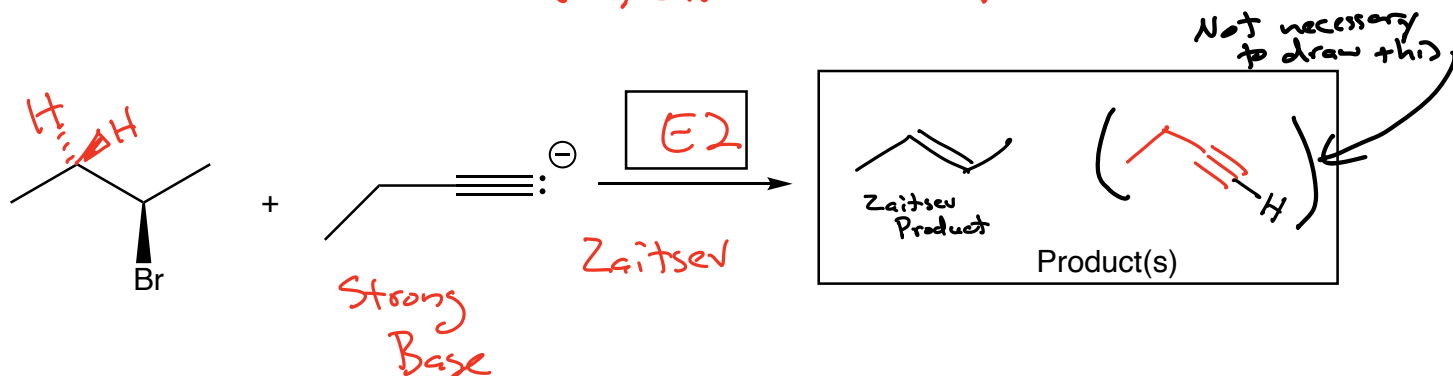

## Primary (1°) Haloalkanes

S<sub>N</sub>2 with all but KOtBu (tBuO<sup>⊖</sup> K<sup>⊕</sup>) → E2

## Secondary (2°) Haloalkanes

→ S<sub>N</sub>2 with all but strong bases or very weak bases  
→ E2 with strong bases  
→ S<sub>N</sub>1/E1 with very weak bases

### Tertiary (3°) Haloalkanes

## E2 Reaction Considerations:

When analyzing highly substituted haloalkanes for a possible E2 reaction:

1. You need to identify the most stable possible alkene (most highly substituted, *trans* over *cis*) that could be made (Zaitsev product).

2. Given the Zaitsev product you have identified, verify which anti-periplanar H atom(s) can be removed during the reaction to determine whether the product is E or Z.
3. You often need to rotate bonds to identify the particular H atom and configuration that reacts to give the alkene product.

Putting it all together:

## E2 Reaction of cyclohexane derivatives:

When analyzing highly substituted haloalkanes for a possible E2 reaction:

1. You need to identify the most stable possible alkene (most highly substituted, *trans* over *cis*) that could be made (Zaitsev product).
2. Given the Zaitsev product you have identified, verify which anti-periplanar H atom(s) can be removed during the reaction to determine if that product can be made.
3. You often need to flip chairs in cyclohexane derivatives to identify the particular H atom and configuration that reacts to give the alkene product.

**Rule:** The halogen must be axial to react via E2 in cyclohexane derivatives

Classic Examples:

not the one predicted by Zaitsev!

## S<sub>N</sub>2 Reactions of Cyclohexanes:

**Rule:** The halogen must be axial to react in an S<sub>N</sub>2 mechanism in a cyclohexane derivative.

## Bloom's Taxonomy of Learning

## Bloom's Taxonomy of Learning

## Organic Chemistry Analog

A) **You must have your entire roadmap learned** so you can recite the NIRRS parameters for each reagent, i.e. Nature of overall transformation ("locations" on the roadmap), the Intermediate or transition state (carbocation, anti-periplanar etc.), the Reagents and how to designate them, as well as any Regiochemistry (Markovnikov, etc.) and any appropriate Stereochemistry (syn, anti, InVERSiON, scrambled, etc).

B) **Work backwards** (learn to RECOGNIZE the appropriate reagents and starting materials by looking at the products) from the final product. DO NOT try to work forward from the starting materials. Please trust me on this.

C) **Count carbons** in the starting material(s) and product(s) to see if any carbon-carbon bonds need to be broken or made, thereby zeroing in on key steps. This will be far more important next semester, so you should get used to doing this now.

D) **Pretty much all synthesis problems in OChem 1 involve traveling "north or south" on the so-called "I-35"** reactions (alkanes SA, haloalkanes NB/SM, alkenes ATX, vicinal dihaloalkanes Waco, alkynes DFW) at least part way at some point during the synthesis. This is not a promise or a rule, just an observation.

20. These are synthesis questions. You need to show how the starting material can be converted into the product(s) shown. You may use any reactions we have learned provided that the product(s) you draw for each step is/are the predominant one(s). Show all the reagents you need. Show each molecule synthesized along the way and be sure to pay attention to the regiochemistry and stereochemistry preferences for each reaction. You must draw all stereoisomers formed, and use wedges and dashes to indicate chirality at each chiral center. Write racemic when appropriate. **All the carbons of the product must come from carbons of the starting material.**

A) (7 pts)

B) (4 pts)

20. These are synthesis questions. You need to show how the starting material can be converted into the product(s) shown. You may use any reactions we have learned provided that the product(s) you draw for each step is/are the predominant one(s). Show all the reagents you need. Show each molecule synthesized along the way and be sure to pay attention to the regiochemistry and stereochemistry preferences for each reaction. You must draw all stereoisomers formed, and use wedges and dashes to indicate chirality at each chiral center. Write racemic when appropriate. **All the carbons of the product must come from carbons of the starting material.**

**Recognize:** The product is a *trans* dichlorocyclohexane that must result from the reaction of an alkene (cyclohexene) with Cl<sub>2</sub>. **Recognize:** The cyclohexene comes from the usual "1-35" combination of halogenation of an alkane with light (the only reaction that uses an alkane starting material) followed by an E2 in strong base such as an alkoxide (NaOR).

20. These are synthesis questions. You need to show how the starting material can be converted into the product(s) shown. You may use any reactions we have learned provided that the product(s) you draw for each step is/are the predominant one(s). Show all the reagents you need. Show each molecule synthesized along the way and be sure to pay attention to the regiochemistry and stereochemistry preferences for each reaction. You must draw all stereoisomers formed, and use wedges and dashes to indicate chirality at each chiral center. Write racemic when appropriate. **All the carbons of the product must come from carbons of the starting material.**

**Recognize:** The product is an aldehyde that can be made from a primary alcohol, ozonolysis of an alkene (breaks carbon-carbon bond so not possible here) or from an alkyne. Choose the latter because an alkyne can be made from the starting vicinal dihaloalkane using base, in this case three equivalents of NaNH<sub>2</sub> followed by mild acid workup because the product is a terminal alkyne.
